# Overview

- 1 Introduction
- 2 History
- 3 X-ray Binaries
- 4 Summary

# Introduction

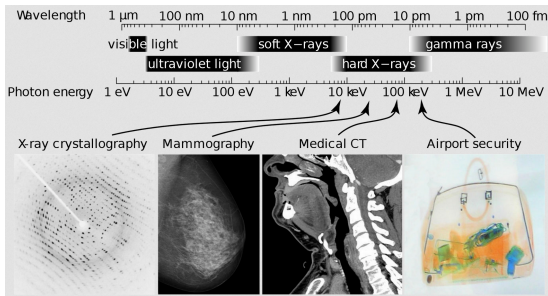

**Figure 1:** Electromagnetic transmittance of Earth's atmosphere. NASA (original); SVG by Mysid.

- 1894, Nikola Tesla noticed damaged film in his lab associated with Crookes tube experiments and began investigating this invisible, radiant energy.
- 1895, German physics professor Wilhelm Röntgen stumbled on X-rays while experimenting with Lenard tubes and Crookes tubes.
- 1904, John Ambrose Fleming invented the thermionic diode, the first kind of vacuum tube.

**Figure 2:** print of Wilhelm Röntgen's first "medical" X-ray, of his wife's hand, taken on 22 December 1895 and presented to Ludwig Zehnder of the Physik Institut, University of Freiburg, on 1 January 1896

# Applications

**Figure 3:** The wavelengths and photon energies of X-rays and a few applications of X-rays.

# Applications

**Figure 3:** The wavelengths and photon energies of X-rays and a few applications of X-rays.

The Chandra X-ray Observatory, launched on July 23, 1999, has been allowing the exploration of the very violent processes in the universe which produce X-ray

# X-ray Binaries

- They provide ideal opportunities for probing the core-collapse of massive stars in a binary environment.

# X-ray Binaries

- They provide ideal opportunities for probing the core-collapse of massive stars in a binary environment.
- Revealed by persistent/transient X-ray activity which is triggered by mass accretion.

# X-ray Binaries

- They provide ideal opportunities for probing the core-collapse of massive stars in a binary environment.
- Revealed by persistent/transient X-ray activity which is triggered by mass accretion.
- Observationally: Pulsars, Neutron Stars and Black Holes.

# X-ray Binaries

- They provide ideal opportunities for probing the core-collapse of massive stars in a binary environment.
- Revealed by persistent/transient X-ray activity which is triggered by mass accretion.
- Observationally: Pulsars, Neutron Stars and Black Holes.

X-ray Binaries classified according to the donor mass:

- Low Mass X-ray Binaries (LMXBs):  
Fueled by accretion discs by a  $\lesssim 1M_{\odot}$  Roche-lobe filling star.

# X-ray Binaries

- They provide ideal opportunities for probing the core-collapse of massive stars in a binary environment.
- Revealed by persistent/transient X-ray activity which is triggered by mass accretion.
- Observationally: Pulsars, Neutron Stars and Black Holes.

X-ray Binaries classified according to the donor mass:

- Low Mass X-ray Binaries (LMXBs):  
Fueled by accretion discs by a  $\lesssim 1M_{\odot}$  Roche-lobe filling star.
- High Mass X-ray Binaries (HMXBs):  
Fed directly from the winds of a  $\gtrsim 10M_{\odot}$  companion.

# X-ray Binaries

Distinct Galactic distributions associated with Population I and Population II objects:

- HMXBs → lying along Galactic plane
- LMXBs → clustering towards the Galactic bulge and in globular clusters.

Figure 4: Galactic Distribution of HMXBs (top) and LMXBs(bottom).  
X-ray Binaries J.Casares 2017

# X-ray activity

X-ray activity observed is determined by:

- 1 Mass transfer rate from donor
- 2 Magnetic field of the compact star
- 3 X-ray heating of accretion disc

X-ray activity observed is determined by:

- 1 Mass transfer rate from donor
- 2 Magnetic field of the compact star
- 3 X-ray heating of accretion disc

The interplay between these three quantities explains:

- Black Hole remnants  $\rightarrow$  transient LMXBs
- Neutron stars  $\rightarrow$  persistent LMXBs
- Pulsars  $\rightarrow$  HMXBs

# Xray Binaries: Remnant Masses

By building the mass spectrum of compact objects in X-ray binaries we can therefore obtain new insights onto the physics of core-collapse in Type Ibc and Type II supernovae

# Pulsar masses in HMXBs

Doppler shift of the donor's photospheric lines, combined with timing delays of the neutron star pulse, allows us to measure the projected orbital velocities of the two binary components  $\rightarrow K_{opt}$  and  $K_X$  respectively.

Doppler shift of the donor's photospheric lines, combined with timing delays of the neutron star pulse, allows us to measure the projected orbital velocities of the two binary components  $\rightarrow K_{opt}$  and  $K_X$  respectively. If pulsar is eclipsed by the massive donor then the inclination angle  $i$  is given by:

$$\sin(i) = \frac{\sqrt{1 - (R_{opt}/a)^2}}{\cos(\theta)} \quad (1)$$

- $\theta$ : eclipse half-angle,  $a$ : Binary separation and  $R_{opt}$  the stellar radius.
- $R_{opt}$  approximated by “filling factor”  $\beta \leq 1$  of the effective Roche Lobe radius  $R_{Lopt}$ .

- $R_{Lopt}/a$  is purely a function of the binary mass ratio

$$Q = M_X/M_{opt} = K_{opt}/K_X$$

Then, the stellar masses can be solved from the mass function equations:

$$M_{opt} = \frac{K_X^3 P (1 - e^2)^{3/2}}{2\pi G \sin^3(i)} (1 + Q)^2 \quad (2)$$

$$M_X = \frac{K_{opt}^3 P (1 - e^2)^{3/2}}{2\pi G \sin^3(i)} \left(1 + \frac{1}{Q}\right)^2 \quad (3)$$

$P$  is the binary period and  $e$  the orbital eccentricity.

This method has produced nine pulsar masses with relatively high precision listed in Figure 5

# Pulsar masses in HMXBs

| Object           | X-ray Binary Class | Remnant      | Mass ( $M_{\odot}$ )   |

Figure 5: Pulsar and Neutron Star masses in X-ray Binaries. X-ray Binaries  
J.Casares 2017

# Neutron Star Masses in LMXBs

Do not usually pulse.

# Neutron Star Masses in LMXBs

Do not usually pulse.

Only the mass function of compact star is attainable through the radial velocity curve of the optical companion (Eq 3).

# Neutron Star Masses in LMXBs

Do not usually pulse.

Only the mass function of compact star is attainable through the radial velocity curve of the optical companion (Eq 3).

Still possible to derive reliable masses by exploiting the fact that low-mass donor star overflows its Roche Lobe and is synchronized in a circular orbit. Broadening of the donor absorption lines depends on binary mass ratio

$q = Q^{-1}$ :

$$V \sin(i) / K_{opt} \simeq 0.462 q^{1/3} (1 + q)^{2/3} \quad (4)$$

# Neutron Star Masses in LMXBs

Do not usually pulse.

Only the mass function of compact star is attainable through the radial velocity curve of the optical companion (Eq 3).

Still possible to derive reliable masses by exploiting the fact that low-mass donor star overflows its Roche Lobe and is synchronized in a circular orbit.

Broadening of the donor absorption lines depends on binary mass ratio

$q = Q^{-1}$ :

$$V \sin(i) / K_{opt} \simeq 0.462 q^{1/3} (1 + q)^{2/3} \quad (4)$$

Therefore, the detection of the faint donor star in LMXBs ensures full dynamical solution which makes this technique feasible for transient LMXBs in quiescence or persistent LMXBs with long orbital periods and thus luminous companion stars.

# Neutron star masses in HMXBs

Figure 6: Pulsar and Neutron Star masses in X-ray Binaries. X-ray Binaries  
J.Casares 2017

# Black hole masses

Great majority found in transient LMXBs/IMXBs.

Relatively precise masses have been measured in quiescence through exploiting the photometric and spectroscopic detection of the companion star.

# Black hole masses in HMXBs

Figure 7: Black hole masses in X-ray Binaries. X-ray Binaries J. Casares 2017

# Mass Spectrum. Implications for Supernovae Models

**Figure 8:** Top: Compact remnant masses measured in X-ray Binaries. Bottom: Observed distributions. X-ray Binaries J. Casares 2017

# Mass Spectrum. Implications for Supernovae Models

Three main features:

- Neutron star masses tend to be larger in LMXBs/IMXBs than in HMXBs

# Mass Spectrum. Implications for Supernovae Models

Three main features:

- Neutron star masses tend to be larger in LMXBs/IMXBs than in HMXBs
- Gap appears between  $\sim 2 - 5M_{\odot}$

# Mass Spectrum. Implications for Supernovae Models

Three main features:

- Neutron star masses tend to be larger in LMXBs/IMXBs than in HMXBs
- Gap appears between  $\sim 2 - 5 M_{\odot}$
- Most massive black holes found in HMXBs

# Mass Spectrum. Implications for Supernovae Models

- 1 Difference in neutron star masses, would stem from different binary evolution histories, with neutron stars in LMXBs having experienced significant accretion over extended periods of time

# Mass Spectrum. Implications for Supernovae Models

- ① Difference in neutron star masses, would stem from different binary evolution histories, with neutron stars in LMXBs having experienced significant accretion over extended periods of time
- ② The lack of compact remnants in the gap contrasts with numerical simulations of Supernovae explosions that lead to continuous distributions. Proposed that convection instabilities, growing within 200 ms after core bounce, can successfully revive supernovae shock and trigger the explosion, causing the gap.

# Mass Spectrum. Implications for Supernovae Models

- 1 Difference in neutron star masses, would stem from different binary evolution histories, with neutron stars in LMXBs having experienced significant accretion over extended periods of time
- 2 The lack of compact remnants in the gap contrasts with numerical simulations of Supernovae explosions that lead to continuous distributions. Proposed that convection instabilities, growing within 200 ms after core bounce, can successfully revive supernovae shock and trigger the explosion, causing the gap.
- 3 Reflects different binary evolutionary paths, with black holes in LMXBs being limited to  $\lesssim 12M_{\odot}$  by severe mass loss from the Wolf-Rayet progenitor after common envelope phase.

# Mass Spectrum. Implications for Supernovae Models

Note: Some aspects of binary and massive stellar evolution (e.g radial expansion, wind mass-loss rates, efficiency of common envelope ejection) are still quite uncertain , which limits our understanding of the formation of X-ray Binaries.
